## IN THE CLAIMS

- 1.(Previously presented) A terminal structure for interconnecting coil ends in a plural phase rotary electrical machine having a shaft rotatable about an axis and adapted to be mounted at one axial end of a core having a plurality of circumferentially spaced pole teeth around which electrical coils are wound, said terminal structure comprising a plurality of conductors equal in number to at least the number of phases and bonded in spaced axially spaced relationship to each other, each of said conductors having terminal ends extending radially outwardly beyond the bonding material and having wire receiving recesses therein for receiving a coil wire end from a respective one of said coil windings, substantially all of said wire receiving recesses lying in a common axial plane.
- 2. (Original) A terminal structure as set forth in claim 1 wherein substantially all of the terminal receiving recesses open in the same direction.
- 3. (Original) A terminal structure as set forth in claim 2 wherein all of the terminal receiving recesses lie in the same common plane and face in the same direction.
- 4. (Original) A terminal structure as set forth in claim 3 wherein the terminal receiving recesses open axially.
- 5 (Original) A terminal structure as set forth in claim 4 wherein the terminal receiving recesses are configured to strip insulation from the coil wire ends when received therein.
- 6. (Original) A terminal structure as set forth in claim 3 wherein the terminal receiving recesses open radially.
- 7. (Currently amended) A terminal structure as set forth in claim 3 wherein the terminal receiving recesses are defined by angularly related leg portions that can be crimped to retain the coil wire end.
  - 8. (Cancelled)
- 9. (Previously presented) A terminal structure as set forth in claim 1 wherein each of the phase is comprised of a plurality of interconnected conductors each lying in the same axial plane and having at least two circumferentially spaced terminal end portions for receiving a coil wire end from a respective one of said coil windings.

10. (Currently amended) A terminal structure for interconnecting coil ends in a plural phase rotary electrical machine and adapted to be mounted at one axial end of a core having a plurality of circumferentially spaced pole teeth around which electrical coils are wound, said terminal structure comprising a plurality of interconnected conductors equal in number to at least the number of phases and bonded in spaced relationship to each other, the interconnected conductors of each of said phase being comprised of a plurality of interconnected conductors cach having at least two circumferentially spaced terminal end portions for receiving a coil wire end from a respective one of said coil windings.

- 11. (Original) A terminal structure as set forth in claim 10 wherein the phases are axially spaced from each other.
- 12. (Previously presented) A terminal structure as set forth in claim 11 wherein each phasespecific terminal member is made of plural connecting pieces comprised of arcs of concentric circles.
- 13. (Currently amended) A terminal structure as set forth in claim 40 11 wherein the interconnected conductors of each of the phases all lie in a common axial plane.
